PESTICIDES

Pesticides are chemical agents used for controlling pests such as insects, diseases or weeds. They are often classified according to their target, and terms such as herbicides, insecticides and fungicides are used synonymously with pesticide. Pesticides are also classified according to chemical class such as organochlorines, organophosphates, and carbonates. The most common application of these chemicals is for crop protection. Despite their protective attributes, pesticides are potentially toxic to humans and to other exposed creatures. The adverse effects can range from acute; irritation of the skin and eyes, and respiratory difficulties, to chronic; endocrine disruption, reproductive problems and cancer. There is evidence linking pesticide exposure to birth defects, foetal death and neurodevelopmental disorder. Pesticides frequently come into contact with targets beyond those intended, including other species, air, water and soil, and are therefore also an environmental concern. In particular chlorinated pesticides, which exhibit bioaccumulation and can build up to harmful levels, and persist in the body and environment for many years. For these reasons pesticides are widely regulated and maximum levels of pesticide residues in food are stipulated, necessitating their analytical measurement.
